

● VPPA Settlement Estimator

Executive Brief - How the platform works and why it matters

Price Settlements
ERCOT VPPA Analytics

What The App Does

- Calculates interval, monthly, and annual VPPA net settlement outcomes in ERCOT.
- Compares SCED Actual, modeled generation, and settlement invoice actuals side by side.
- Shows capture price, implied REC cost, and settlement deltas for fast variance diagnosis.

Core Data Inputs

- ERCOT RTM hub prices for interval settlement pricing.
- ERCOT 60-day SCED disclosure for asset-level actual dispatch and generation.
- Project metadata (location, capacity, turbine mix) and uploaded invoice data.

Modeling Approach

- Weather-driven generation model using Open-Meteo/PVGIS by default with actual weather mode.
- Wind engine supports Standard and Advanced Calibrated configurations.
- Optional SCED Base Point cap aligns modeled output to observed dispatch constraints.

How Settlement Is Computed

- Interval energy (MWh) is multiplied by settlement spread versus strike price.
- Upside-share setting controls how positive spread is split; downside remains fully exposed.
- Outputs include interval cashflow plus monthly and annual rollups with full traceability.

Why Executives Use It

- Explains monthly settlement variance by separating price, generation, and model effects.
- Accelerates invoice reconciliation with transparent interval-level evidence.
- Improves decision speed for risk, origination, and contract governance teams.

Known Constraints

- SCED public data is lagged, so latest available is not always current date.
- Final accounting should still follow signed contract language and counterparty invoice rules.
